Sitka Spruce / Salal / Western Sword Fern

Épinette de Sitka / Salal / Fougère épée

Subassociations: none

CNVC Alliance: not yet determined

CNVC Group: not yet determined

Type Description

Concept: Sitka spruce (*Picea sitchensis*) is prominent in this productive, shoreline, coniferous forest association, where exposure to salt spray is pronounced. CNVC00057 occurs near sea level on wind-exposed sandy marine terraces and lower slope topopositions within the very wet hypermaritime climate regime of the outer Pacific coast. Soils are generally mesic to moist and relatively fertile. Sitka spruce is often accompanied in the canopy by variable coverage of western hemlock (*Tsuga heterophylla*) and western redcedar (*Thuja plicata*). Common species in the shrub layer include salal (*Gaultheria shallon*), salmonberry (*Rubus spectabilis*), red huckleberry (*Vaccinium parvifolium*), and regenerating tree species. When sufficient light is available, the herb layer usually features western sword fern (*Polystichum munitum*), deer fern (*Blechnum spicant*), two-leaved false Solomon's seal (*Maianthemum dilatatum*), clasping-leaved twisted-stalk (*Streptopus amplexifolius*), and bracken fern (*Pteridium aquilinum*). The relatively diverse moss layer includes slender beaked moss (*Eurhynchium praelongum*), Oregon beaked moss (*E. oregonum*), shining clear moss (*Hookeria lucens*), dotted leafy moss (*Rhizomnium punctatum*), flat moss (*Plagiothecium undulatum*) and hairy pouchwort (*Calypogeja trichomanis*).

Vegetation: CNVC00057 is a productive, shoreline coniferous forest association. *Picea sitchensis* is typically the leading canopy species, especially on sites exposed to salt spray or mist, accompanied by variable minor coverage of *Tsuga heterophylla* and *Thuja plicata*. The latter species increase in importance, at the expense of *Picea sitchensis*, as the salt influence declines with distance from the spray zone. *Gaultheria shallon*, *Rubus spectabilis*, *Vaccinium parvifolium* and regenerating tree species dominate the variable shrub layer. The herb layer is likewise variably sparse to well-developed, depending on the intensity of overstory shading. Common herb species include *Polystichum munitum*, *Blechnum spicant*, *Maianthemum dilatatum*, *Streptopus amplexifolius*, and *Pteridium aquilinum*. The moss layer is relatively species-rich, reflecting the moist shoreline conditions with salt and other mineral inputs, but generally without high cover. Common species include *Eurhynchium praelongum*, *E. oregonum*, *Hookeria lucens*, *Rhizomnium punctatum*, *Plagiothecium undulatum* and *Calypogeja trichomanis*.

Environment: CNVC00057 occurs in very wet hypermaritime climates on sandy marine terraces and lower slope topopositions. Sites supporting this association occur near sea level where there is exposure to salt spray and mist. The mesic to moist, nutrient-rich soils are Humo-Ferric Podzols, Dystric Brunisols and Regosols, with mor humus forms.

***Picea sitchensis* / *Gaultheria shallon* / *Polystichum munitum* CNVC00057**

Type Description (cont'd)

Dynamics: CNVC00057 is a shoreline forest association of the outer Pacific coast. Strong winds shape the stands and individual trees, and also influence stand density by causing windthrow and tree breakage. In addition to wind, natural disturbance agents include root disease and insect-caused mortality, which may result in small canopy gaps. Old stands exhibit gap dynamics and an all-aged structure. Stand-destroying windstorms are rare. Fires are not a significant factor in this hypermaritime climate. This association can currently be found in an old-forest stage only within coastal protected areas, otherwise it occurs in young or mature forest stages due to logging or human settlement activities.

Range: CNVC00057 occurs near sea level in a narrow shoreline band along the outer west coast of Vancouver Island. It may occur on the adjacent outer mainland coast of British Columbia northward to near Rivers Inlet. It is also distributed south on the Olympic Peninsula of Washington State, USA.

Conservation Status (NatureServe)

Relationships with Other Classifications:

Comments

Picea sitchensis is resistant to salt spray-induced needle burn and die-back damage, and can tolerate greater salinity in soil solution than other conifer species. Furthermore, its higher nutritional requirements for calcium, magnesium and phosphorus appear to make it more suitable to higher salinity environments, where these elements are concentrated.

Several *Picea sitchensis*-dominated, shoreline forest associations occur along the exposed, outer coastline of British Columbia. CNVC00016 [*Picea sitchensis* / *Gaultheria shallon* / *Maianthemum dilatatum*] differs from CNVC00057 by the dense understory of *Gaultheria shallon*. Rocky headlands and old sand dunes may have an association of *Picea sitchensis* - *Calamagrostis nootkatensis*, as yet undescribed in the CNVC.
