Type Description

Concept: CNVC00310 is a boreal coniferous forest Association that occurs in New Brunswick, Nova Scotia and insular Newfoundland. It has a closed canopy dominated by balsam fir (*Abies balsamea*), often with minor presence of paper birch (*Betula papyrifera*). The shrub layer varies from poorly to moderately developed and consists mainly of regenerating balsam fir. A dense herb layer with abundant wood ferns (*Dryopteris carthusiana*, *D. campyloptera* and/or *D. intermedia*) characterizes this Association. The prominence of shaded wood moss (*Hylocomiastrum umbratum*) and greater broom moss (*Dicranum majus*) along with red-stemmed feathermoss (*Pleurozium schreberi*) and knight's plume moss (*Ptilium crista-castrensis*) in the well-developed moss layer is also distinctive. CNVC00310 occurs in a region with a humid to very humid, maritime-influenced boreal climate. It is typically found on mesic to moist, nutrient-medium to rich sites. These are some of the most productive sites in the region. It is a late successional condition that occurs where fire has been absent for a long period. Windthrow and insect outbreaks are the primary natural disturbances. Canopy gaps or large patches that result from these disturbances promote self-replacement of this Association by the release of balsam fir regeneration. Four subassociations are recognized: *Hylocomium splendens*, *Rhytidiadelphus loreus*, *Cornus stolonifera* and *Oxalis montana*.

Vegetation: CNVC00310 is a coniferous forest Association with a closed canopy dominated by *Abies balsamea*, usually with low abundance of *Betula papyrifera* (see Comments) and/or *Picea glauca*. The poorly developed shrub layer is dominated by *A. balsamea* regeneration. A dense herb layer with abundant *Dryopteris* spp., including *D. carthusiana*, *D. campyloptera* and/or *D. intermedia*, characterizes this Association. Other species that are common amidst the ferns include *Lysimachia borealis*, *Maianthemum canadense*, *Cornus canadensis* and *Clintonia borealis*. The moss layer is usually well developed and typically includes *Pleurozium schreberi*, *Ptilium crista-castrensis*, *Hylocomiastrum umbratum* and *Dicranum majus*.

Four subassociations are distinguished: *Hylocomium splendens*, *Rhytidiadelphus loreus*, *Cornus stolonifera* and *Oxalis montana*. The moss layer of the *Hylocomium splendens* subassociation is dominated by *H. splendens*, with lower cover of *P. schreberi* and *D. majus*. Where this subassociation occurs within the limited range of *Betula alleghaniensis* in Newfoundland, it occasionally has minor cover of *B. alleghaniensis* in the tree or shrub layers. The *Rhytidiadelphus loreus* subassociation has a dense moss layer dominated by *R. loreus*, *H. umbratum* and *D. majus*. The *Cornus stolonifera* subassociation is characterized by *C. stolonifera* in the shrub layer, and very high cover of *D. carthusiana* in the herb layer. The *Oxalis montana* subassociation is differentiated by the abundance of this forb and greater cover of *D. campyloptera* and *D. intermedia* relative to *D. carthusiana*.

Type Description (cont'd)

Environment: CNVC00310 occurs in a humid to very humid, maritime-influenced boreal climate where regional fire cycles are long (270-500 years) or very long (>500 years). It is found most frequently on mesic to moist, nutrient-medium to rich sites; these are among the most productive sites in this region of the boreal. Stands are usually on level sites or gentle to moderate slopes, often on cooler aspects (either east or north-facing). Soils are typically coarse-textured, well-drained and derived from morainal parent materials. Seepage enhances the moisture and nutrient availability on these sites. Mor humus forms are typical.

There are site distinctions among the four subassociations. The *Hylocomium splendens* subassociation occurs more frequently on mesic slopes than do the other subassociations, which are most common on moist level sites. The *Rhytidiadelphus loreus* subassociation occurs where moist shallow tills cover limestone bedrock in western Newfoundland. Where its range overlaps with the *Hylocomium splendens* subassociation, the *Rhytidiadelphus loreus* subassociation occurs at higher elevations.

Dynamics: CNVC00310 is a stable self-perpetuating late successional forest Association. Wildfires are generally absent from its range but strong winds are frequent, often causing local windthrow gaps. Insect defoliation by spruce budworm (*Choristoneura fumiferana*) and hemlock looper (*Lambdina fiscellaria fiscellaria*) is common in these forests, particularly in the mature to senescent stages of stand development, and can lead to extensive canopy mortality. While insect disturbance has considerable impact on the commercial yields of timber, it rarely has long-term consequences for ecosystem composition and structure in these forests. Following disturbance (including harvesting), stands tend to recover by release of understory *Abies balsamea* regeneration. Small-scale gap or patch disturbances typically result in an uneven age structure within stands, but severe broad-scale disturbance can create large openings that release understory trees that are more or less the same age.

When fires do occur, they are usually of anthropogenic origin and are rarely extensive. Fire eliminates *A. balsamea*; early seral hardwoods such as *Betula papyrifera* and *B. alleghaniensis* are likely to dominate the initial post-fire stand on these sites (e.g., CNVC00315 [*Betula papyrifera* – *B. alleghaniensis* / *Dryopteris carthusiana*]). Over time, as humus builds up in a stand, *A. balsamea* seedlings are better able to establish and survive in the low-light environment than are *Betula* seedlings; *A. balsamea* persists in the understory as advanced regeneration until being released by further canopy disturbance. Thus, these sites usually return to *A. balsamea* dominance over time.

Abies balsamea regeneration is heavily grazed by moose (*Alces alces*) in some locations, so these stands can have a relatively higher cover of *Picea glauca*, which is not grazed to the same extent.

Range: CNVC00310 occurs in the boreal highlands of northern New Brunswick and Cape Breton Island, Nova Scotia, and on insular Newfoundland. Three subassociations are described from Newfoundland: the *Hylocomium splendens* subassociation occurs in southwestern and central Newfoundland, the *Rhytidiadelphus loreus* subassociation is known from southwestern Newfoundland, and the *Cornus stolonifera* subassociation is described from the Northern Peninsula. The *Oxalis montana* subassociation is described from New Brunswick and Cape Breton Island.

Related Concepts

Similar CNVC Associations:

CNVC00222 [*Abies balsamea* / *Pleurozium schreberi*] occurs on mesic, nutrient-medium sites in the same range. It has a less developed herb layer with lower abundance of *Dryopteris* spp., and a moss layer dominated by *Pleurozium schreberi*.

CNVC00225 [*Abies balsamea* (*Picea glauca*) / *Acer spicatum* / *Oxalis montana*] occurs on comparable boreal sites in New Brunswick, Nova Scotia and Quebec. It has more *Picea glauca* in the canopy and abundant *Acer spicatum* in the shrub layer.

CNVC00278 [*Abies balsamea* / *Pleurozium schreberi* – *Sphagnum* spp.] usually occurs on moister, slightly poorer sites on insular Newfoundland. It often has a minor component of *Picea mariana* in the tree and shrub layers, less developed shrub and herb layers and abundant *Sphagnum* mosses.

CNVC00309 [*Abies balsamea* / *Vaccinium vitis-idaea* / *Pleurozium schreberi* – *Bazzania trilobata*] occurs on dry to mesic, nutrient-poor to medium boreal sites in Nova Scotia and insular Newfoundland. It lacks the *Dryopteris* spp. of CNVC00310 and has greater *Gaultheria hispidula* and *Vaccinium vitis-idaea* in the herb and dwarf shrub layer. It usually has abundant *Pleurozium schreberi* and *Bazzania trilobata* in the moss layer.

CNVC00311 [*Abies balsamea* (*Betula alleghaniensis*) / *Dryopteris carthusiana*] is a similar mixedwood Association that occurs on comparable sites on insular Newfoundland. It has greater cover of *Betula alleghaniensis* and/or *B. papyrifera* in the overstory and a less developed moss layer.

CNVC00348 [*Abies balsamea* / *Taxus canadensis* / *Rubus pubescens* / *Dicranum majus*] occurs on moist, nutrient-rich sites on insular Newfoundland. It is often found down-slope from CNVC00310 in a toposequence where it receives more seepage and consequently has greater abundance of nutrient-demanding species such as *Cornus stolonifera*, *Rubus pubescens*, *Gymnocarpium dryopteris*, *Athyrium filix-femina* and *Mitella nuda*.

Related United States National Vegetation Classification Associations:

Relationships with Other Classifications:

Nova Scotia plots in CNVC00310 are classified as HL1 [Balsam fir / Mountain-ash / Large-leaved goldenrod] in Neily et al. 2011.

CNVC00310 includes the concepts of Fdl #8 Dryopteris – Lycopodium – Balsam fir, Fdh #5 Dryopteris – Hylocomium – Balsam fir and Fdr #7 Dryopteris – Rhytidadelphus – Balsam fir, and elements of Fd#6 Dryopteris – Balsam fir from Meades & Moores 1994.

Comments

In the general context of boreal forests, this Association, and particularly the *Hylocomium splendens* subassociation, is notable for its content of *Betula alleghaniensis*, which is usually considered a temperate species. CNVC00310 lacks understory species typically associated with temperate forests however, so is classified here as a boreal forest Association.

CNVC00310 rarely develops in the more continental interior of Newfoundland where fire is more frequent.

Betula papyrifera here refers to both *B. papyrifera* (paper birch) and *B. cordifolia* (heart-leaved birch).
